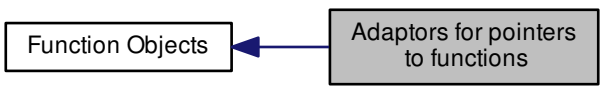
2.1 Adaptors for pointers to functions

Collaboration diagram for Adaptors for pointers to functions:



Classes

- class std::pointer_to_binary_function< _Arg1, _Arg2, _Result >
- class std::pointer_to_unary_function< _Arg, _Result >

Functions

- template<typename _Arg , typename _Result >
  pointer_to_unary_function
  < _Arg, _Result > std::ptr_fun (_Result(*__x)(_Arg))
- template<typename _Arg1 , typename _Arg2 , typename _Result >
  pointer_to_binary_function
  < _Arg1, _Arg2, _Result > std::ptr_fun (_Result(*__x)(_Arg1, _Arg2))

2.1.1 Detailed Description

The advantage of function objects over pointers to functions is that the objects in the standard library declare nested typedefs describing their argument and result types with uniform names (e.g., `result_type` from the base classes `unary_function` and `binary_function`). Sometimes those typedefs are required, not just optional.

Adaptors are provided to turn pointers to unary (single-argument) and binary (double-argument) functions into function objects. The long-winded functor `pointer_to_unary_function` is constructed with a function pointer `f`, and its `operator()` called with argument `x` returns `f(x)`. The functor `pointer_to_binary_function` does the same thing, but with a double-argument `f` and `operator()`.

The function `ptr_fun` takes a pointer-to-function `f` and constructs an instance of the appropriate functor.

2.1.2 Function Documentation

2.1.2.1 template<typename _Arg , typename _Result > pointer_to_unary_function<_Arg, _Result> std::ptr_fun (_Result(*)(_Arg) __x) [inline]

One of the adaptors for function pointers.

Definition at line 1100 of file stl_function.h.

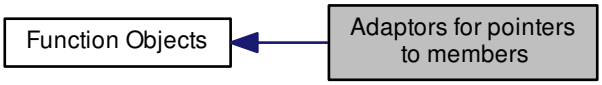
2.1.2.2 template<typename _Arg1 , typename _Arg2 , typename _Result > pointer_to_binary_function<_Arg1, _Arg2, _Result> std::ptr_fun (_Result(*)(_Arg1, _Arg2) __x) [inline]

One of the adaptors for function pointers.

Definition at line 1126 of file stl_function.h.

2.2 Adaptors for pointers to members

Collaboration diagram for Adaptors for pointers to members:



Classes

- class std::const_mem_fun1_ref_t< _Ret, _Tp, _Arg >
- class std::const_mem_fun1_t< _Ret, _Tp, _Arg >
- class std::const_mem_fun_ref_t< _Ret, _Tp >
- class std::const_mem_fun_t< _Ret, _Tp >
- class std::mem_fun1_ref_t< _Ret, _Tp, _Arg >
- class std::mem_fun1_t< _Ret, _Tp, _Arg >
- class std::mem_fun_ref_t< _Ret, _Tp >
- class std::mem_fun_t< _Ret, _Tp >

Functions

- template<typename _Ret , typename _Tp >
  mem_fun_t< _Ret, _Tp > **std::mem_fun** (_Ret(_Tp::*__f)())
- template<typename _Ret , typename _Tp , typename _Arg >
  mem_fun1_t< _Ret, _Tp, _Arg > **std::mem_fun** (_Ret(_Tp::*__f)(_Arg))
- template<typename _Ret , typename _Tp >
  mem_fun_ref_t< _Ret, _Tp > **std::mem_fun_ref** (_Ret(_Tp::*__f)())
- template<typename _Ret , typename _Tp , typename _Arg >
  mem_fun1_ref_t< _Ret, _Tp, _Arg > **std::mem_fun_ref** (_Ret(_Tp::*__f)(_Arg))

2.2.1 Detailed Description

There are a total of 8 = 2^3 function objects in this family. (1) Member functions taking no arguments vs member functions taking one argument. (2) Call through pointer vs call through reference. (3) Const vs non-const member function.

All of this complexity is in the function objects themselves. You can ignore it by using the helper function mem_fun and mem_fun_ref, which create whichever type of adaptor is appropriate.

2.15.1 Detailed Description

These algorithms are variations of a classic binary search, and all assume that the sequence being searched is already sorted.

The number of comparisons will be logarithmic (and as few as possible). The number of steps through the sequence will be logarithmic for random-access iterators (e.g., pointers), and linear otherwise.

The LWG has passed Defect Report 270, which notes: *The proposed resolution reinterprets binary search. Instead of thinking about searching for a value in a sorted range, we view that as an important special case of a more general algorithm: searching for the partition point in a partitioned range. We also add a guarantee that the old wording did*

not: we ensure that the upper bound is no earlier than the lower bound, that the pair returned by equal_range is a valid range, and that the first part of that pair is the lower bound.

The actual effect of the first sentence is that a comparison functor passed by the user doesn't necessarily need to induce a strict weak ordering relation. Rather, it partitions the range.

2.15.2 Function Documentation

2.15.2.1 template<typename _ForwardIterator , typename _Tp > constexpr bool std::binary_search (_ForwardIterator *__first,* _ForwardIterator *__last,* const _Tp & *__val*)

Determines whether an element exists in a range.

Parameters

__first	An iterator.
__last	Another iterator.
__val	The search term.

Returns

True if `__val` (or its equivalent) is in [`__first`,`__last`].

Note that this does not actually return an iterator to `__val`. For that, use std::find or a container's specialized find member functions.

Definition at line 2262 of file stl_algo.h.

2.15.2.2 template<typename _ForwardIterator , typename _Tp , typename _Compare > constexpr bool std::binary_search (_ForwardIterator *__first,* _ForwardIterator *__last,* const _Tp & *__val,* _Compare *__comp*)

Parameters

__first	An iterator.
__last	Another iterator.
__val	The search term.
__comp	A functor to use for comparisons.

Returns

True if `__val` (or its equivalent) is in [__first,__last].

Note that this does not actually return an iterator to `__val`. For that, use std::find or a container's specialized find member functions.

The comparison function should have the same effects on ordering as the function used for the initial sort.

Definition at line 2296 of file stl_algo.h.

This is equivalent to

```
std::make_pair(lower_bound(__first, __last, __val),
               upper_bound(__first, __last, __val))
```

but does not actually call those functions.

```
std::make_pair(lower_bound(__first, __last, __val, __comp),
               upper_bound(__first, __last, __val, __comp))
```

but does not actually call those functions.

Parameters

__first	An iterator.

__last	Another iterator.

Definition at line 1348 of file stl_algobase.h.

2.15.2.6 template<typename _ForwardIterator , typename _Tp , typename _Compare > constexpr _ForwardIterator std::lower_bound (_ForwardIterator *__first,* _ForwardIterator *__last,* const _Tp & *__val,* _Compare *__comp*) [inline]

Parameters

__first	An iterator.
__last	Another iterator.
__val	The search term.

Parameters

__first	An iterator.
__last	Another iterator.
__val	The search term.
__comp	A functor to use for comparisons.

Returns

An iterator pointing to the first element greater than `__val`, or end() if no elements are greater than `__val`.

2.16.1 Detailed Description

Binders turn functions/functors with two arguments into functors with a single argument, storing an argument to be applied later. For example, a variable `B` of type `binder1st` is constructed from a functor `f` and an argument `x`. Later, B's `operator()` is called with a single argument `y`. The return value is the value of `f(x,y)`. `B` can be *called* with various arguments (y1, y2, ...) and will in turn call `f(x,y1)`, `f(x,y2)`, ...

The function `bind1st` is provided to save some typing. It takes the function and an argument as parameters, and returns an instance of `binder1st`.

The type `binder2nd` and its creator function `bind2nd` do the same thing, but the stored argument is passed as the second parameter instead of the first, e.g., `bind2nd`(std::minus<float>(),1.3) will create a functor whose `operator()` accepts a floating-point number, subtracts 1.3 from it, and returns the result. (If `bind1st` had been used, the functor would perform *1.3 - x* instead.

Creator-wrapper functions like `bind1st` are intended to be used in calling algorithms. Their return values will be temporary objects. (The goal is to not require you to type names like `std::binder1st<std::plus<int>>` for declaring a variable to hold the return value from `bind1st(std::plus<int>(),5)`.

These become more useful when combined with the composition functions.

These functions are deprecated in C++11 and can be replaced by `std::bind` (or `std::tr1::bind`) which is more powerful and flexible, supporting functions with any number of arguments. Uses of `bind1st` can be replaced by `std::bind(f, x, std::placeholders::_1)` and `bind2nd` by `std::bind(f, std::placeholders::_1, x)`.

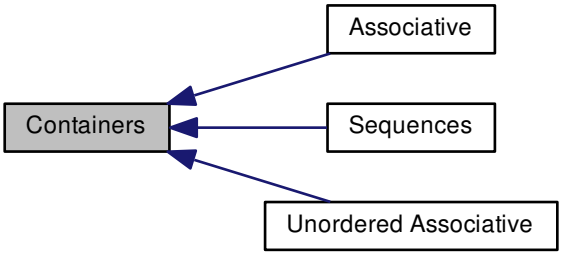
2.25 Containers

Collaboration diagram for Containers:



Modules

- Associative
- Sequences
- Unordered Associative

2.25.1 Detailed Description

Containers are collections of objects.

A container may hold any type which meets certain requirements, but the type of contained object is chosen at compile time, and all objects in a given container must be of the same type. (Polymorphism is possible by declaring a container of pointers to a base class and then populating it with pointers to instances of derived classes. Variant value types such as the `any` class from `Boost` can also be used.

All contained types must be `Assignable` and `CopyConstructible`. Specific containers may place additional requirements on the types of their contained objects.

Containers manage memory allocation and deallocation themselves when storing your objects. The objects are destroyed when the container is itself destroyed. Note that if you are storing pointers in a container, `delete` is *not* automatically called on the pointers before destroying them.

All containers must meet certain requirements, summarized in `tables`.

The standard containers are further refined into Sequences and Associative Containers. Unordered Associative Containers.

2.34.1 Detailed Description

Function objects, or *functors*, are objects with an `operator()` defined and accessible. They can be passed as arguments to algorithm templates and used in place of a function pointer. Not only is the resulting expressiveness of the library increased, but the generated code can be more efficient than what you might write by hand. When we refer to *functors*, then, generally we include function pointers in the description as well.

Often, functors are only created as temporaries passed to algorithm calls, rather than being created as named variables.

Two examples taken from the standard itself follow. To perform a by-element addition of two vectors `a` and `b` containing `double`, and put the result in `a`, use

```
transform (a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
```

To negate every element in `a`, use

```
transform(a.begin(), a.end(), a.begin(), negate<double>());
```

The addition and negation functions will be inlined directly.

The standard functors are derived from structs named `unary_function` and `binary_function`. These two classes contain nothing but typedefs, to aid in generic (template) programming. If you write your own functors, you might consider doing the same.

2.34.2.1 template<typename _Tp , typename _Class > constexpr _Mem_fn<_Tp _Class::*> std::mem_fn (_Tp _Class::* __pm) [inline], [noexcept]

2.41.1 Detailed Description

Nearly all of the I/O classes are parameterized on the type of characters they read and write. (The major exception is ios_base at the top of the hierarchy.) This is a change from pre-Standard streams, which were not templates.

For ease of use and compatibility, all of the basic_* I/O-related classes are given typedef names for both of the builtin character widths (wide and narrow). The typedefs are the same as the pre-Standard names, for example:

```
typedef basic_ifstream<char>  ifstream;
```

Because properly forward-declaring these classes can be difficult, you should not do it yourself. Instead, include the <iosfwd> header, which contains only declarations of all the I/O classes as well as the typedefs. Trying to forward-declare the typedefs themselves (e.g., `class ostream;`) is not valid ISO C++.

For more specific declarations, see https://gcc.gnu.org/onlinedocs/libstdc++/manual/io.-html#std.io.objects

2.43.1 Detailed Description

These are empty types, used to distinguish different iterators. The distinction is not made by what they contain, but simply by what they are. Different underlying algorithms can then be used based on the different operations supported by different iterator types.

2.44.1 Detailed Description

Abstractions for uniform iterating through various underlying types.

2.44.2 Function Documentation

2.44.2.1 template<typename _Iter > constexpr iterator_traits<_Iter>::iterator_category std::__iterator_category (const _Iter &) [inline]

This function is not a part of the C++ standard but is syntactic sugar for internal library use only.

Definition at line 238 of file stl_iterator_base_types.h.

Referenced by std::__find_if_not(), __gnu_debug::__valid_range_aux(), std::advance(), std::deque< _StateSeqT >::assign(), __gnu_cxx::copy_n(), std::copy_n(), std::deque< _StateSeqT >::deque(), __gnu_cxx::distance(), std::distance(), std::fill_n(), std::find_end(), std::deque< _StateSeqT >::insert(), std::partition(), std::reverse(), std::__V2::rotate(), __gnu_cxx::uninitialized_copy_n(), std::uninitialized_copy_n(), std::unique_copy(), and std::vector< block_type, allocator_type >::vector().

2.44.2.2 template<typename _Container > constexpr back_insert_iterator<_Container> std::back_inserter (_Container & __x) [inline]

Parameters

__x	A container of arbitrary type.

Returns

An instance of back_insert_iterator working on __x.

This wrapper function helps in creating back_insert_iterator instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 685 of file bits/stl_iterator.h.

Referenced by std::match_results< _Bi_iter >::format(), and std::regex_replace().

2.44.2.3 template<typename _Container > constexpr front_insert_iterator<_Container> std::front_inserter (_Container & __x) [inline]

Parameters

__x	A container of arbitrary type.

Returns

An instance of front_insert_iterator working on x.

This wrapper function helps in creating front_insert_iterator instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 788 of file bits/stl_iterator.h.

2.44.2.4 template<typename _Container , typename _Iterator > insert_iterator<_Container> std::inserter (_Container & __x, _Iterator __i) [inline]

Parameters

__x	A container of arbitrary type.
__i	An iterator into the container.

Returns

An instance of insert_iterator working on __x.

This wrapper function helps in creating insert_iterator instances. Typing the name of the iterator requires knowing the precise full type of the container, which can be tedious and impedes generic programming. Using this function lets you take advantage of automatic template parameter deduction, making the compiler match the correct types for you.

Definition at line 931 of file bits/stl_iterator.h.

2.44.2.5 template<typename _Iterator > constexpr reverse_iterator<_Iterator> std::make_reverse_iterator (_Iterator __i) [inline]

Generator function for reverse_iterator.

Definition at line 552 of file bits/stl_iterator.h.

2.44.2.6 template<typename _Iterator > constexpr bool std::operator== (const reverse_iterator< _Iterator > & __x, const reverse_iterator< _Iterator > & __y) [inline]

Parameters

__x	A reverse_iterator.
__y	A reverse_iterator.

Returns

A simple bool.

Reverse iterators forward comparisons to their underlying base() iterators.

Definition at line 385 of file bits/stl_iterator.h.

References std::reverse_iterator< _Iterator >::base().

2.47.1 Detailed Description

Classes and functions for internationalization and localization.

2.47.2 Function Documentation

2.47.2.1 template<typename _Facet > bool std::has_facet (const locale & __loc) throw)

Test for the presence of a facet.

has_facet tests the locale argument for the presence of the facet type provided as the template parameter. Facets derived from the facet parameter will also return true.

Template Parameters

_Facet	The facet type to test the presence of.

Parameters

__loc	The locale to test.

Returns

true if `__loc` contains a facet of type _Facet, else false.

Definition at line 104 of file locale_classes.tcc.

2.47.2.2 template<typename _Facet > const _Facet & std::use_facet (const locale & __loc)

Return a facet.

use_facet looks for and returns a reference to a facet of type Facet where Facet is the template parameter. If has_facet(locale) is true, there is a suitable facet to return. It throws std::bad_cast if the locale doesn't contain a facet of type Facet.

Template Parameters

_Facet	The facet type to access.

Parameters

__loc	The locale to use.

Returns

Reference to facet of type Facet.

Exceptions

std::bad_cast	if `__loc` doesn't contain a facet of type _Facet.

Definition at line 132 of file locale_classes.tcc.

2.48.1 Detailed Description

2.48.2 Mathematical Special Functions

A collection of advanced mathematical special functions, defined by ISO/IEC IS 29124 and then added to ISO C++ 2017.

2.48.2.1 Introduction and History

The first significant library upgrade on the road to C++2011, TR1, included a set of 23 mathematical functions that significantly extended the standard transcendental functions inherited from C and declared in <cmath>.

Although most components from TR1 were eventually adopted for C++11 these math functions were left behind out of concern for implementability. The math functions were published as a separate international standard IS 29124 - Extensions to the C++ Library to Support Mathematical Special Functions.

For C++17 these functions were incorporated into the main standard.

2.48.2.2 Contents

The following functions are implemented in namespace `std`:

- assoc_laguerre - Associated Laguerre functions
- assoc_legendre - Associated Legendre functions
- beta - Beta functions
- comp_ellint_1 - Complete elliptic functions of the first kind

- comp_ellint_2 - Complete elliptic functions of the second kind
- comp_ellint_3 - Complete elliptic functions of the third kind
- cyl_bessel_i - Regular modified cylindrical Bessel functions
- cyl_bessel_j - Cylindrical Bessel functions of the first kind
- cyl_bessel_k - Irregular modified cylindrical Bessel functions
- cyl_neumann - Cylindrical Neumann functions or Cylindrical Bessel functions of the second kind
- ellint_1 - Incomplete elliptic functions of the first kind
- ellint_2 - Incomplete elliptic functions of the second kind
- ellint_3 - Incomplete elliptic functions of the third kind
- expint - The exponential integral
- hermite - Hermite polynomials
- laguerre - Laguerre functions
- legendre - Legendre polynomials
- riemann_zeta - The Riemann zeta function
- sph_bessel - Spherical Bessel functions
- sph_legendre - Spherical Legendre functions
- sph_neumann - Spherical Neumann functions

The hypergeometric functions were stricken from the TR29124 and C++17 versions of this math library because of implementation concerns. However, since they were in the TR1 version and since they are popular we kept them as an extension in namespace `__gnu_cxx`:

- conf_hyperg - Confluent hypergeometric functions
- hyperg - Hypergeometric functions

2.48.2.3 Argument Promotion

The arguments suppled to the non-suffixed functions will be promoted according to the following rules:

1. If any argument intended to be floating point is given an integral value That integral value is promoted to double.
2. All floating point arguments are promoted up to the largest floating point precision among them.

2.48.2.4 NaN Arguments

If any of the floating point arguments supplied to these functions is invalid or NaN (std::numeric_limits<Tp>::quiet_NaN), the value NaN is returned.

2.48.2.5 Implementation

We strive to implement the underlying math with type generic algorithms to the greatest extent possible. In practice, the functions are thin wrappers that dispatch to function templates. Type dependence is controlled with std::numeric_limits and functions thereof.

We don't promote `float` to `double` or `double` to `long double` reflexively. The goal is for `float` functions to operate more quickly, at the cost of `float` accuracy and possibly a smaller domain of validity. Similaryly, `long double` should give you more dynamic range and slightly more pecision than `double` on many systems.

2.48.2.6 Testing

These functions have been tested against equivalent implementations from the Gnu Scientific Library, GSL and Boost and the ratio

$$\frac{|f - f_{test}|}{|f_{test}|}$$

is generally found to be within 10^{-15} for 64-bit double on linux-x86_64 systems over most of the ranges of validity.

Todo Provide accuracy comparisons on a per-function basis for a small number of targets.

2.49.2.1 void* std::align (size_t *__align*, size_t *__size*, void *&* *__ptr*, size_t & *__space*) [inline], [noexcept]

Fit aligned storage in buffer.

This function tries to fit *__size* bytes of storage with alignment *__align* into the buffer *__ptr* of size *__space* bytes. If such a buffer fits then *__ptr* is changed to point to the first byte of the aligned storage and *__space* is reduced by the bytes used for alignment.

C++11 20.6.5 [ptr.align]

Parameters

__align	A fundamental or extended alignment value.
__size	Size of the aligned storage required.
__ptr	Pointer to a buffer of *__space* bytes.
__space	Size of the buffer pointed to by *__ptr*.

Returns

the updated pointer if the aligned storage fits, otherwise nullptr.

Definition at line 123 of file memory.

2.49.2.2 template<typename _InputIterator , typename _ForwardIterator > _ForwardIterator std::uninitialized_copy (_InputIterator *__first*, _InputIterator *__last*, _ForwardIterator *__result*) [inline]

Copies the value x into the range [first,last).

Parameters

__first	An input iterator.
__last	An input iterator.
__x	The source value.

Returns

Nothing.

Like fill(), but does not require an initialized output range.

Definition at line 200 of file stl_uninitialized.h.

2.49.2.5 template<typename _ForwardIterator , typename _Size , typename _Tp > _ForwardIterator std::uninitialized_fill_n (_ForwardIterator *__first,* _Size *__n,* const _Tp & *__x*) [inline]

Copies the value x into the range [first,first+n).

Parameters

__first	An input iterator.
__n	The number of copies to make.
__x	The source value.

2.51.1 Detailed Description

2.51.2 Function Documentation

2.51.2.1 template<typename _II , typename _OI > constexpr _OI std::copy (_II *__first,* _II *__last,* _OI *__result*) [inline]

Copies the range [first,last) into result.

Parameters

__first	An input iterator.
__last	An input iterator.
__result	An output iterator.

Returns

result + (last - first)

This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling). Result may not be contained within [first,last); the copy_backward function should be used instead.

Note that the end of the output range is permitted to be contained within [first,last).

Definition at line 560 of file stl_algobase.h.

2.51.2.2 template<typename _BI1 , typename _BI2 > constexpr _BI2 std::copy_backward (_BI1 *__first,* _BI1 *__last,* _BI2 *__result*) [inline]

Copies the range [first,last) into result.

Parameters

__first	A bidirectional iterator.
__last	A bidirectional iterator.
__result	A bidirectional iterator.

Returns

result - (last - first)

The function has the same effect as copy, but starts at the end of the range and works its way to the start, returning the start of the result. This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Result may not be in the range (first,last]. Use copy instead. Note that the start of the output range may overlap [first,last).

Definition at line 797 of file stl_algobase.h.

Referenced by std::deque< _Tp, _Alloc >::_M_reallocate_map().

2.51.2.3 template<typename _InputIterator , typename _OutputIterator , typename _Predicate > constexpr _OutputIterator std::copy_if (_InputIterator __first, _InputIterator __last, _OutputIterator __result, _Predicate __pred)

Copy the elements of a sequence for which a predicate is true.

Parameters

__first	An input iterator.
__last	An input iterator.
__result	An output iterator.
__pred	A predicate.

Returns

An iterator designating the end of the resulting sequence.

Copies each element in the range [__first,__last) for which __pred returns true to the range beginning at __result.

copy_if() is stable, so the relative order of elements that are copied is unchanged.

Definition at line 688 of file stl_algo.h.

2.51.2.4 template<typename _InputIterator , typename _Size , typename _OutputIterator > constexpr _OutputIterator std::copy_n (_InputIterator *__first,* _Size *__n,* _OutputIterator *__result*) [inline]

Copies the range [first,first+n) into [result,result+n).

Parameters

__first	An input iterator.
__n	The number of elements to copy.
__result	An output iterator.

Returns

result+n.

This inline function will boil down to a call to memmove whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Definition at line 768 of file stl_algo.h.

References std::__iterator_category().

2.51.2.5 template<typename _ForwardIterator , typename _Tp > constexpr void std::fill (_ForwardIterator *__first,* _ForwardIterator *__last,* const _Tp & *__value*) [inline]

Fills the range [first,last) with copies of value.

Parameters

__first	A forward iterator.
__last	A forward iterator.
__value	A reference-to-const of arbitrary type.

Returns

Nothing.

This function fills a range with copies of the same value. For char types filling contiguous areas of memory, this becomes an inline call to memset or wmemset.

Definition at line 937 of file stl_algobase.h.

2.51.2.6 template<typename _OI , typename _Size , typename _Tp > constexpr _OI std::fill_n (_OI *__first,* _Size *__n,* const _Tp & *__value*) [inline]

Fills the range [first,first+n) with copies of value.

Parameters

__first	An output iterator.
__n	The count of copies to perform.
__value	A reference-to-const of arbitrary type.

Returns

The iterator at first+n.

This function fills a range with copies of the same value. For char types filling contiguous areas of memory, this becomes an inline call to `memset` or `wmemset`.

If `__n` is negative, the function does nothing.

Definition at line 1089 of file stl_algobase.h.

References std::__iterator_category().

2.51.2.7 template<typename _ForwardIterator , typename _Generator > constexpr void std::generate (_ForwardIterator *__first*, _ForwardIterator *__last*, _Generator *__gen*)

Assign the result of a function object to each value in a sequence.

Parameters

__first	A forward iterator.
__last	A forward iterator.
__gen	A function object taking no arguments and returning std::iterator_traits<_ForwardIterator>-::value_type

Returns

generate() returns no value.

Performs the assignment `*i = __gen()` for each `i` in the range [__first,__last).

Definition at line 4441 of file stl_algo.h.

2.51.2.8 template<typename _OutputIterator , typename _Size , typename _Generator > constexpr _OutputIterator std::generate_n (_OutputIterator *__first*, _Size *__n*, _Generator *__gen*)

Assign the result of a function object to each value in a sequence.

Parameters

__first	A forward iterator.
__n	The length of the sequence.
__gen	A function object taking no arguments and returning std::iterator_traits<_ForwardIterator>-::value_type

Returns

The end of the sequence, `__first+__n`

Performs the assignment `*i = __gen()` for each `i` in the range [__first,__first+__n).

If `__n` is negative, the function does nothing and returns `__first`.

Definition at line 4475 of file stl_algo.h.

2.51.2.9 template<typename _InputIterator , typename _Predicate > constexpr bool std::is_partitioned (_InputIterator *__first,* _InputIterator *__last,* _Predicate *__pred*) [inline]

Checks whether the sequence is partitioned.

Parameters

__first	An input iterator.
__last	An input iterator.
__pred	A predicate.

Returns

True if the range [__first,__last) is partioned by __pred, i.e. if all elements that satisfy __pred appear before those that do not.

Definition at line 530 of file stl_algo.h.

References std::find_if_not(), and std::none_of().

2.51.2.10 template<typename _ForwardIterator1 , typename _ForwardIterator2 > constexpr void std::iter_swap (_ForwardIterator1 *__a,* _ForwardIterator2 *__b*) [inline]

Swaps the contents of two iterators.

Parameters

__a	An iterator.
__b	Another iterator.

Returns

Nothing.

This function swaps the values pointed to by two iterators, not the iterators themselves.

Definition at line 152 of file stl_algobase.h.

Referenced by std::__merge_without_buffer(), std::__move_median_to_first(), std::__partition(), std::__reverse(), std::__unguarded_partition(), std::random_shuffle(), std::shuffle(), and std::swap_ranges().

2.51.2.11 template<typename _II , typename _OI > constexpr _OI std::move (_II *__first,* _II *__last,* _OI *__result*) [inline]

Moves the range [first,last) into result.

Parameters

__first	An input iterator.
__last	An input iterator.
__result	An output iterator.

Returns

result + (last - first)

This inline function will boil down to a call to memmove whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling). Result may not be contained within [first,last); the move_backward function should be used instead.

Note that the end of the output range is permitted to be contained within [first,last).

Definition at line 593 of file stl_algobase.h.

2.51.2.12 template<typename _BI1 , typename _BI2 > constexpr _BI2 std::move_backward (_BI1 *__first,* _BI1 *__last,* _BI2 *__result*) [inline]

Parameters

__first	A bidirectional iterator.
__last	A bidirectional iterator.
__result	A bidirectional iterator.

Returns

result - (last - first)

The function has the same effect as move, but starts at the end of the range and works its way to the start, returning the start of the result. This inline function will boil down to a call to `memmove` whenever possible. Failing that, if random access iterators are passed, then the loop count will be known (and therefore a candidate for compiler optimizations such as unrolling).

Result may not be in the range (first,last]. Use move instead. Note that the start of the output range may overlap [first,last).

Definition at line 833 of file stl_algobase.h.

2.51.2.13 template<typename _ForwardIterator , typename _Predicate > constexpr _ForwardIterator std::partition (_ForwardIterator *__first*, _ForwardIterator *__last*, _Predicate *__pred*) [inline]

Move elements for which a predicate is true to the beginning of a sequence.

Parameters

Returns

An iterator `middle` such that `__pred(i)` is true for each iterator `i` in the range [__first,middle) and false for each `i` in the range [middle,__last).

`__pred` must not modify its operand. `partition()` does not preserve the relative ordering of elements in each group, use `stable_partition()` if this is needed.

Definition at line 4663 of file stl_algo.h.

References std::__iterator_category(), and std::__partition().

2.51.2.14 template<typename _InputIterator , typename _OutputIterator1 , typename _OutputIterator2 , typename _Predicate > constexpr pair<_OutputIterator1, _OutputIterator2> std::partition_copy (_InputIterator *__first*, _InputIterator *__last*, _OutputIterator1 *__out_true*, _OutputIterator2 *__out_false*, _Predicate *__pred*)

Find the partition point of a partitioned range.

Parameters

__first	An iterator.
__last	Another iterator.
__pred	A predicate.

Returns

An iterator mid such that all_of(__first, mid, __pred) and none_of(mid, __last, __pred) are both true.

Definition at line 552 of file stl_algo.h.

References std::advance(), and std::distance().

2.51.2.16 template<typename _RandomAccessIterator , typename _RandomNumberGenerator > void std::random_shuffle (_RandomAccessIterator *__first*, _RandomAccessIterator *__last*, _RandomNumberGenerator && *__rand*)

Parameters

__first	A forward iterator.
__last	A forward iterator.
__rand	The RNG functor or function.

Returns

Nothing.

Reorders the elements in the range [__first,__last) using __rand to provide a random distribution. Calling __rand(N) for a positive integer N should return a randomly chosen integer from the range [0,N).

Definition at line 4622 of file stl_algo.h.

References std::iter_swap().

Definition at line 1165 of file stl_algo.h.

References std::__iterator_category(), and std::__reverse().

The ranges [__first,__last) and [__result,__result+(__last-__first)) must not overlap.

Definition at line 1193 of file stl_algo.h.

__first	A forward iterator.
__middle	A forward iterator.
__last	A forward iterator.

Returns

first + (last - middle).

This effectively swaps the ranges [__first,__middle) and [__middle,__last).

Performs *(__first+(n+(__last-__middle))%(__last-__first))=*(__first+n) for each `n` in the range [0,__last-__first).

Classes

- class std::binary_negate< _Predicate >
- class std::unary_negate< _Predicate >

Functions

- template<typename _Predicate >
  constexpr unary_negate
  < _Predicate > std::not1 (const _Predicate &__pred)
- template<typename _Predicate >
  constexpr binary_negate
  < _Predicate > std::not2 (const _Predicate &__pred)

2.53.1 Detailed Description

The functions `not1` and `not2` each take a predicate functor and return an instance of `unary_negate` or `binary_negate`, respectively. These classes are functors whose `operator()` performs the stored predicate function and then returns the negation of the result.

For example, given a vector of integers and a trivial predicate,

```
struct IntGreaterThanThree
  : public std::unary_function<int, bool>
{
    bool operator() (int x) { return x > 3; }
};

std::find_if (v.begin(), v.end(), not1(IntGreaterThanThree()));
```

The call to `find_if` will locate the first index (i) of `v` for which `!(v[i] > 3)` is true.

The not1/unary_negate combination works on predicates taking a single argument. The not2/binary_negate combination works on predicates which take two arguments.

2.66.1 Detailed Description

These classes define objects which provide random or pseudorandom numbers, either from a discrete or a continuous interval. The random number generator supplied as a part of this library are all uniform random number generators which provide a sequence of random number uniformly distributed over their range.

A number generator is a function object with an operator() that takes zero arguments and returns a number.

A compliant random number generator must satisfy the following requirements.

To be documented.

2.70.1 Detailed Description

Because libstdc++ based its implementation of the STL subsections of the library on the SGI 3.3 implementation, we inherited their extensions as well.

They are additionally documented in the online documentation, a copy of which is also shipped with the library source code (in .../docs/html/documentation.html). You can also read the documentation on SGI's site, which is still running even though the code is not maintained.

NB that the following notes are pulled from various comments all over the place, so they may seem stilted.

The identity_element functions are not part of the C++ standard; SGI provided them as an extension. Its argument is an operation, and its return value is the identity element for that operation. It is overloaded for addition and multiplication, and you can overload it for your own nefarious operations.

As an extension to the binders, SGI provided composition functors and wrapper functions to aid in their creation. The unary_compose functor is constructed from two functions/functors, f and g. Calling operator() with a single argument x returns f(g(x)). The function compose1 takes the two functions and constructs a unary_compose variable for you.

binary_compose is constructed from three functors, f, g1, and g2. Its operator() returns f(g1(x),g2(x)). The function compose2 takes f, g1, and g2, and constructs the binary_compose instance for you. For example, if f returns an int, then

```
int answer = (compose2(f,g1,g2))(x);
```

is equivalent to

```
int temp1 = g1(x);
int temp2 = g2(x);
int answer = f(temp1,temp2);
```

But the first form is more compact, and can be passed around as a functor to other algorithms.

As an extension, SGI provided a functor called identity. When a functor is required but no operations are desired, this can be used as a pass-through. Its operator() returns its argument unchanged.

select1st and select2nd are extensions provided by SGI. Their operator()s take a std::pair as an argument, and return either the first member or the second member, respectively. They can be used (especially with the composition functors) to *strip* data from a sequence before performing the remainder of an algorithm.

The operator() of the project1st functor takes two arbitrary arguments and returns the first one, while project2nd returns the second one. They are extensions provided by SGI.

These three functors are each constructed from a single arbitrary variable/value. Later, their operator()s completely ignore any arguments passed, and return the stored value.

- constant_void_fun's operator() takes no arguments
- constant_unary_fun's operator() takes one argument (ignored)
- constant_binary_fun's operator() takes two arguments (ignored)

The helper creator functions constant0, constant1, and constant2 each take a *result* argument and construct variables of the appropriate functor type.

- class std::stack< _Tp, _Sequence >
- class std::vector< _Tp, _Alloc >
- class std::vector< bool, _Alloc >

2.71.1 Detailed Description

Sequences arrange a collection of objects into a strictly linear order.

The differences between sequences are usually due to one or both of the following:

- memory management
- algorithmic complexity

As an example of the first case, `vector` is required to use a contiguous memory layout, while other sequences such as `deque` are not.

The prime reason for choosing one sequence over another should be based on the second category of differences, algorithmic complexity. For example, if you need to perform many inserts and removals from the middle of a sequence, `list` would be ideal. But if you need to perform constant-time access to random elements of the sequence, then `list` should not be used.

All sequences must meet certain requirements, summarized in `tables`.

2.72.1 Detailed Description

These algorithms are common set operations performed on sequences that are already sorted. The number of comparisons will be linear.

2.72.2 Function Documentation

2.72.2.1 template<typename _InputIterator1 , typename _InputIterator2 > constexpr bool std::includes (_InputIterator1 *__first1,* _InputIterator1 *__last1,* _InputIterator2 *__first2,* _InputIterator2 *__last2*) [inline]

Determines whether all elements of a sequence exists in a range.

Parameters

__first1	Start of search range.
__last1	End of search range.
__first2	Start of sequence
__last2	End of sequence.

Returns

True if each element in [__first2,__last2) is contained in order within [__first1,__last1). False otherwise.

This operation expects both [__first1,__last1) and [__first2,__last2) to be sorted. Searches for the presence of each element in [__first2,__last2) within [__first1,__last1). The iterators over each range only move forward, so this is a linear algorithm. If an element in [__first2,__last2) is not found before the search iterator reaches `__last2`, false is returned.

Definition at line 2840 of file stl_algo.h.

2.72.2.2 template<typename _InputIterator1 , typename _InputIterator2 , typename _Compare > constexpr bool std::includes (_InputIterator1 *__first1,* _InputIterator1 *__last1,* _InputIterator2 *__first2,* _InputIterator2 *__last2,* _Compare *__comp*) [inline]

Determines whether all elements of a sequence exists in a range using comparison.

Parameters

__first1	Start of search range.
__last1	End of search range.
__first2	Start of sequence
__last2	End of sequence.
__comp	Comparison function to use.

Returns

True if each element in [__first2,__last2) is contained in order within [__first1,__last1) according to comp. False otherwise.

This operation expects both [__first1,__last1) and [__first2,__last2) to be sorted. Searches for the presence of each element in [__first2,__last2) within [__first1,__last1), using comp to decide. The iterators over each range only move forward, so this is a linear algorithm. If an element in [__first2,__last2) is not found before the search iterator reaches `__last2`, false is returned.

Definition at line 2886 of file stl_algo.h.

2.72.2.3 template<typename _InputIterator1 , typename _InputIterator2 , typename _OutputIterator > constexpr _OutputIterator std::set_difference (_InputIterator1 *__first1,* _InputIterator1 *__last1,* _InputIterator2 *__first2,* _InputIterator2 *__last2,* _OutputIterator *__result*) [inline]

Return the difference of two sorted ranges.

Parameters

__first1	Start of first range.
__last1	End of first range.
__first2	Start of second range.
__last2	End of second range.
__result	Start of output range.

Returns

End of the output range.

This operation iterates over both ranges, copying elements present in the first range but not the second in order to the output range. Iterators increment for each range. When the current element of the first range is less than the second, that element is copied and the iterator advances. If the current element of the second range is less, the iterator advances, but no element is copied. If an element is contained in both ranges, no elements are copied and both ranges advance. The output range may not overlap either input range.

Return the difference of two sorted ranges using comparison functor.

Parameters

__first1	Start of first range.
__last1	End of first range.
__first2	Start of second range.
__last2	End of second range.
__result	Start of output range.
__comp	The comparison functor.

Returns

This operation iterates over both ranges, copying elements present in the first range but not the second in order to the output range. Iterators increment for each range. When the current element of the first range is less than the second according to __comp, that element is copied and the iterator advances. __last2	End of second range.
__result	Start of output range.

Returns

This operation iterates over both ranges, copying elements present in each range in order to the output range. Iterators increment for each range. When the current element of one range is less than the other, that element is copied and the iterator advanced. If an element is contained in both ranges, the element from the first range is copied and both ranges advance. The output range may not overlap either input range.

Returns

End of the output range.

This operation iterates over both ranges, copying elements present in each range in order to the output range. Iterators increment for each range. When the current element of one range is less than the other according to `__comp`, that element is copied and the iterator advanced. If an equivalent element according to `__comp` is contained in both ranges, the element from the first range is copied and both ranges advance. The output range may not overlap either input range.

2.73.1 Detailed Description

2.73.2 Function Documentation

2.73.2.1 template<typename _BidirectionalIterator > void std::inplace_merge (_BidirectionalIterator *__first,* _BidirectionalIterator *__middle,* _BidirectionalIterator *__last*) [inline]

Merges two sorted ranges in place.

Parameters

__first	An iterator.
__middle	Another iterator.
__last	Another iterator.

Returns

Nothing.

Merges two sorted and consecutive ranges, [__first,__middle) and [__middle,__last), and puts the result in [__first,__last). The output will be sorted. The sort is *stable*, that is, for equivalent elements in the two ranges, elements from the first range will always come before elements from the second.

If enough additional memory is available, this takes (__last-__first)-1 comparisons. Otherwise an NlogN algorithm is used, where N is distance(__first,__last).

Definition at line 2585 of file stl_algo.h.

2.73.2.2 template<typename _BidirectionalIterator , typename _Compare > void std::inplace_merge (_BidirectionalIterator *__first,* _BidirectionalIterator *__middle,* _BidirectionalIterator *__last,* _Compare *__comp*) [inline]

Merges two sorted ranges in place.

Parameters

__first	An iterator.
__middle	Another iterator.
__last	Another iterator.
__comp	A functor to use for comparisons.

Returns

Nothing.

Merges two sorted and consecutive ranges, [__first,__middle) and [middle,last), and puts the result in [__first,__last). The output will be sorted. The sort is *stable*, that is, for equivalent elements in the two ranges, elements from the first range will always come before elements from the second.

If enough additional memory is available, this takes (__last-__first)-1 comparisons. Otherwise an NlogN algorithm is used, where N is distance(__first,__last).

The comparison function should have the same effects on ordering as the function used for the initial sort.

Definition at line 2626 of file stl_algo.h.

Parameters

Sorts the smallest (__middle-__first) elements in the range [__first,__last) and moves them to the range [__first,__middle). The order of the remaining elements in the range [__middle,__last) is undefined. After the sort if *i* and *j* are iterators in the range [__first,__middle) such that i precedes j and *k* is an iterator in the range [__middle,__last) then ∗__comp(j,∗i) and __comp(∗k,∗i) are both false.

Definition at line 4736 of file stl_algo.h.

2.73.2.29 template<typename _InputIterator , typename _RandomAccessIterator > constexpr _RandomAccessIterator std::partial_sort_copy (_InputIterator *__first,* _InputIterator *__last,* _RandomAccessIterator *__result_first,* _RandomAccessIterator *__result_last*) [inline]

Copy the smallest elements of a sequence.

Parameters

__first	An iterator.
__last	Another iterator.
__result_first	A random-access iterator.
__result_last	Another random-access iterator.

Returns

An iterator indicating the end of the resulting sequence.

Copies and sorts the smallest N values from the range [__first,__last) to the range beginning at __result_first, where the number of elements to be copied, N, is the smaller of (__last-__first) and (__result_last-__result_first). After the sort if *i* and *j* are iterators in the range [__result_first,__result_first+N) such that i precedes j then ∗j<∗i is false. The value returned is __result_first+N.

2.73.2.30 template<typename _InputIterator , typename _RandomAccessIterator , typename _Compare > constexpr _RandomAccessIterator std::partial_sort_copy (_InputIterator *__first,* _InputIterator *__last,* _RandomAccessIterator *__result_first,* _RandomAccessIterator *__result_last,* _Compare *__comp*) [inline]

Copy the smallest elements of a sequence using a predicate for comparison.

Parameters

__first	An input iterator.
__last	Another input iterator.
__result_first	A random-access iterator.
__result_last	Another random-access iterator.
__comp	A comparison functor.

Returns

An iterator indicating the end of the resulting sequence.

Copies and sorts the smallest N values from the range [__first,__last) to the range beginning at `result_first`, where the number of elements to be copied, `N`, is the smaller of (__last-__first) and (__result_last-__result_first). After the sort if *i* and *j* are iterators in the range [__result_first,__result_first+N) such that i precedes j then `__comp(*j,*i)` is false. The value returned is `__result_first+N`.

Definition at line 1784 of file stl_algo.h.

2.73.2.31 template<typename _BidirectionalIterator > constexpr bool std::prev_permutation (_BidirectionalIterator *__first*, _BidirectionalIterator *__last*) [inline]

Permute range into the previous *dictionary* ordering.

Parameters

__first	Start of range.
__last	End of range.

Returns

False if wrapped to last permutation, true otherwise.

Treats all permutations of the range as a set of *dictionary* sorted sequences. Permutes the current sequence into the previous one of this set. Returns true if there are more sequences to generate. If the sequence is the smallest of the set, the largest is generated and false returned.

Definition at line 3074 of file stl_algo.h.

2.73.2.32 template<typename _BidirectionalIterator , typename _Compare > constexpr bool std::prev_permutation (_BidirectionalIterator *__first*, _BidirectionalIterator *__last*, _Compare *__comp*) [inline]

Permute range into the previous *dictionary* ordering using comparison functor.

Parameters

__first	Start of range.
__last	End of range.
__comp	A comparison functor.

Returns

False if wrapped to last permutation, true otherwise.

Treats all permutations of the range [__first,__last) as a set of *dictionary* sorted sequences ordered by `__comp`. Permutes the current sequence into the previous one of this set. Returns true if there are more sequences to generate. If the sequence is the smallest of the set, the largest is generated and false returned.

Definition at line 3107 of file stl_algo.h.

2.73.2.33 template<typename _RandomAccessIterator > constexpr void std::sort (_RandomAccessIterator *__first*, _RandomAccessIterator *__last*) [inline]

Sort the elements of a sequence.

Parameters

__first	An iterator.
__last	Another iterator.

Returns

Nothing.

Sorts the elements in the range [__first,__last) in ascending order, such that for each iterator *i* in the range [__first,__last-1), ∗(i+1)<∗i is false.

The relative ordering of equivalent elements is not preserved, use `stable_sort()` if this is needed.

Definition at line 4851 of file stl_algo.h.

2.73.2.34 template<typename _RandomAccessIterator , typename _Compare > constexpr void std::sort (_RandomAccessIterator *__first,* _RandomAccessIterator *__last,* _Compare *__comp*) [inline]

Sort the elements of a sequence using a predicate for comparison.

Parameters

__first	An iterator.
__last	Another iterator.
__comp	A comparison functor.

Returns

Nothing.

Sorts the elements in the range [__first,__last) in ascending order, such that `__comp`(∗(i+1),∗i) is false for every iterator *i* in the range [__first,__last-1).

The relative ordering of equivalent elements is not preserved, use `stable_sort()` if this is needed.

Definition at line 4882 of file stl_algo.h.

2.73.2.35 template<typename _RandomAccessIterator > void std::stable_sort (_RandomAccessIterator *__first,* _RandomAccessIterator *__last*) [inline]

Sort the elements of a sequence, preserving the relative order of equivalent elements.

Parameters

__first	An iterator.
__last	Another iterator.

Returns

Nothing.

Sorts the elements in the range [__first,__last) in ascending order, such that for each iterator `i` in the range [__first,__last-1), ∗(i+1)<∗i is false.

The relative ordering of equivalent elements is preserved, so any two elements `x` and `y` in the range [__first,__last) such that `x<y` is false and `y<x` is false will have the same relative ordering after calling `stable_sort()`.

Definition at line 5060 of file stl_algo.h.

2.73.2.36 template<typename _RandomAccessIterator , typename _Compare > void std::stable_sort (_RandomAccessIterator *__first,* _RandomAccessIterator *__last,* _Compare *__comp*) [inline]

Sort the elements of a sequence using a predicate for comparison, preserving the relative order of equivalent elements.

Parameters

__first	An iterator.
__last	Another iterator.
__comp	A comparison functor.

Returns

Nothing.

Sorts the elements in the range [__first,__last) in ascending order, such that for each iterator `i` in the range [__first,__last-1), `__comp(*(i+1),*i)` is false.

The relative ordering of equivalent elements is preserved, so any two elements `x` and `y` in the range [__first,__last) such that `__comp(x,y)` is false and `__comp(y,x)` is false will have the same relative ordering after calling `stable_sort()`.

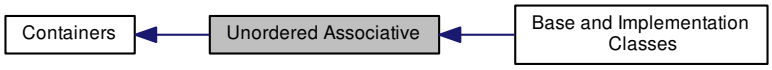
2.83 Unordered Associative

Collaboration diagram for Unordered Associative:



Modules

- Base and Implementation Classes

Classes

- class std::unordered_map< _Key, _Tp, _Hash, _Pred, _Alloc >

- class std::unordered_multiset< _Value, _Hash, _Pred, _Alloc >
- class std::unordered_set< _Value, _Hash, _Pred, _Alloc >

2.83.1 Detailed Description

Unordered associative containers allow fast retrieval of data based on keys.

Each container type is parameterized on a `Key` type, a `Hash` type providing a hashing functor, and an ordering relation used to sort the elements of the container.

All unordered associative containers must meet certain requirements, summarized in `tables`.

2.84.2.16 template<typename _T1 , typename _T2 > constexpr pair< typename __decay_and_strip< _T1 >::__type, typename __decay_and_strip< _T2 >::__type > make_pair (_T1 && __x, _T2 && __y) [related]

A convenience wrapper for creating a pair from two objects.

Parameters

__x	The first object.
__y	The second object.

Returns

A newly-constructed pair<> object of the appropriate type.

The C++98 standard says the objects are passed by reference-to-const, but C++03 says they are passed by value (this was LWG issue #181).

Since C++11 they have been passed by forwarding reference and then forwarded to the new members of the pair. To create a pair with a member of reference type, pass a `reference_wrapper` to this function.

Definition at line 567 of file stl_pair.h.

Parameters

__t	A thing of arbitrary type.

Returns

The parameter cast to an rvalue-reference to allow moving it.

2.84.2.18 template<typename _Tp > constexpr conditional<__move_if_noexcept_cond<_Tp>::value, const _Tp&, _Tp&&>::type std::move_if_noexcept (_Tp & __x) [noexcept]

Conditionally convert a value to an rvalue.

Parameters

__x	A thing of arbitrary type.

Returns

3.1.1 Detailed Description

GNU extensions for public use.

3.1.2 Function Documentation

3.1.2.1 template<typename _ToType , typename _FromType > _ToType __gnu_cxx::__static_pointer_cast (const _FromType & *__arg*) [inline]

Casting operations for cases where _FromType is not a standard pointer. _ToType can be a standard or non-standard pointer. Given that _FromType is not a pointer, it must have a get() method that returns the standard pointer equivalent of the address it points to, and must have an element_type typedef which names the type it points to.

Definition at line 68 of file cast.h.

3.1.2.2 template<typename _ToType , typename _FromType > _ToType __gnu_cxx::__static_pointer_cast (_FromType * *__arg*) [inline]

Casting operations for cases where _FromType is a standard pointer. _ToType can be a standard or non-standard pointer.

Definition at line 96 of file cast.h.

3.1.2.3 std::size_t __gnu_cxx::_Bit_scan_forward (std::size_t *__num*) [inline]

Generic Version of the bsf instruction.

Definition at line 508 of file bitmap_allocator.h.

Referenced by __gnu_cxx::bitmap_allocator< _Tp >::_M_allocate_single_object().

3.1.2.4 template<typename _CharT , typename _Traits , typename _Alloc , template< typename, typename, typename > class _Base> bool __gnu_cxx::operator!= (const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__lhs,* const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__rhs*) [inline]

Test difference of two strings.

Parameters

__lhs	First string.
__rhs	Second string.

Returns

True if *__lhs.compare*(*__rhs*) != 0. False otherwise.

Definition at line 2389 of file vstring.h.

3.1.2.5 template<typename _CharT , typename _Traits , typename _Alloc , template< typename, typename, typename > class _Base> bool __gnu_cxx::operator!= (const _CharT * *__lhs,* const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__rhs*) [inline]

Test difference of C string and string.

Parameters

__lhs	C string.
__rhs	String.

Returns

True if *__rhs.compare*(*__lhs*) != 0. False otherwise.

Definition at line 2402 of file vstring.h.

3.1.2.6 template<typename _CharT , typename _Traits , typename _Alloc , template< typename, typename, typename > class _Base> bool __gnu_cxx::operator!= (const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__lhs,* const _CharT * *__rhs*) [inline]

Test difference of string and C string.

Parameters

__lhs	String.
__rhs	C string.

Returns

True if *__lhs.compare*(*__rhs*) != 0. False otherwise.

Definition at line 2415 of file vstring.h.

3.1.2.7 template<typename _CharT , typename _Traits , typename _Alloc , template< typename, typename, typename > class _Base> __versa_string< _CharT, _Traits, _Alloc, _Base > __gnu_cxx::operator+ (const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__lhs,* const __versa_string< _CharT, _Traits, _Alloc, _Base > & *__rhs*)

Concatenate two strings.

Parameters

__lhs	First string.
__rhs	Last string.

Returns

3.4.1 Detailed Description

GNU debug classes for public use.

3.4.2 Enumeration Type Documentation

3.4.2.1 enum __gnu_debug::_Distance_precision

The precision to which we can calculate the distance between two iterators.

Definition at line 52 of file helper_functions.h.

3.4.3 Function Documentation

3.4.3.1 template<typename _Iterator > constexpr _Iterator __gnu_debug::__base (_Iterator __*it*) [inline]

Helper function to extract base iterator of random access safe iterator in order to reduce performance impact of debug mode. Limited to random access iterator because it is the only category for which it is possible to check for correct iterators order in the __valid_range function thanks to the < operator.

Definition at line 299 of file helper_functions.h.

Referenced by __gnu_parallel::__for_each_template_random_access_workstealing(), std::__detail::__from_chars_digit(), __gnu_debug::_Safe_iterator< _Iterator, _Sequence, std::forward_iterator_tag >::_M_before_dereferenceable(),

3.4.3.2 template<typename _Tp > bool __gnu_debug::__check_singular (_Tp *const & *__ptr*) [inline]

Non-NULL pointers are nonsingular.

Definition at line 130 of file helper_functions.h.

3.4.3.3 bool __gnu_debug::__check_singular_aux (const _Safe_iterator_base * *__x*) [inline]

Iterators that derive from _Safe_iterator_base can be determined singular or non-singular.

Definition at line 168 of file safe_base.h.

References __gnu_debug::_Safe_iterator_base::_M_singular().

3.4.3.4 template<typename _CharT , typename _Integer > const _CharT* __gnu_debug::__check_string (const _CharT * *__s,* _Integer *__n,* const char * *__file,* unsigned int *__line,* const char * *__function*) [inline]

Checks that __s is non-NULL or __n == 0, and then returns __s.

Definition at line 49 of file debug/string.

3.4.3.5 template<typename _CharT > const _CharT* __gnu_debug::__check_string (const _CharT * *__s,* const char * *__file,* unsigned int *__line,* const char * *__function*) [inline]

Checks that __s is non-NULL and then returns __s.

Definition at line 65 of file debug/string.

3.4.3.6 template<typename _Iterator , typename _Sequence , typename _Category , typename _OtherIterator > bool __gnu_debug::__foreign_iterator_aux2 (const _Safe_iterator< _Iterator, _Sequence, _Category > & *__it,* const _Safe_iterator< _OtherIterator, _Sequence, _Category > & *__other,* const _Safe_iterator< _OtherIterator, _Sequence, _Category > &) [inline]

Handle debug iterators from the same type of container.

Definition at line 127 of file functions.h.

Handle debug iterators from different types of container.

Definition at line 138 of file functions.h.

3.4.3.8 template<typename _Iterator > constexpr _Distance_traits<_Iterator>::__type __gnu_debug::__get_distance (_Iterator *__lhs,* _Iterator *__rhs,* **std::random_access_iterator_tag**) [inline]

Determine the distance between two iterators with some known precision.

Definition at line 94 of file helper_functions.h.

3.4.3.9 template<typename _InputIterator > constexpr bool __gnu_debug::__valid_range (_InputIterator *__first,* _InputIterator *__last,* typename _Distance_traits< _InputIterator >::__type & *__dist*) [inline]

Don't know what these iterators are, or if they are even iterators (we may get an integral type for InputIterator), so see if they are integral and pass them on to the next phase otherwise.

Definition at line 225 of file helper_functions.h.

3.4.3.10 template<typename _Iterator , typename _Sequence , typename _Category > bool __gnu_debug::__valid_range (const _Safe_iterator< _Iterator, _Sequence, _Category > & *__first,* const _Safe_iterator< _Iterator, _Sequence, _Category > & *__last,* typename _Distance_traits< _Iterator >::__type & *__dist*) [inline]

Safe iterators know how to check if they form a valid range.

Definition at line 934 of file safe_iterator.h.

3.4.3.11 template<typename _Iterator , typename _Sequence > bool __gnu_debug::__valid_range (const _Safe_local_iterator< _Iterator, _Sequence > & *__first,* const _Safe_local_iterator< _Iterator, _Sequence > & *__last,* typename _Distance_traits< _Iterator >::__type & *__dist_info*) [inline]

Safe local iterators know how to check if they form a valid range.

Definition at line 407 of file safe_local_iterator.h.

3.4.3.12 template<typename _Integral > constexpr bool __gnu_debug::__valid_range_aux (_Integral , _Integral , std::__true_type) [inline]

We say that integral types for a valid range, and defer to other routines to realize what to do with integral types instead of iterators.

Definition at line 140 of file helper_functions.h.

Referenced by __valid_range(), and __valid_range_aux().

3.4.3.13 template<typename _InputIterator > constexpr bool __gnu_debug::__valid_range_aux (_InputIterator *__first,* _InputIterator *__last,* std::__false_type) [inline]

We have iterators, so figure out what kind of iterators they are to see if we can check the range ahead of time.

Definition at line 181 of file helper_functions.h.

__gnu_parallel::_Settings::find_block_size There are two main differences between the growing blocks and the constant-size blocks variants.

1. For GB, the block size grows; for CSB, the block size is fixed.
2. For GB, the blocks are allocated dynamically; for CSB, the blocks are allocated in a predetermined manner, namely spacial round-robin.

Multiway Merge Frontend.

Merge the sequences specified by seqs_begin and __seqs_end into __target. __seqs_begin and __seqs_end must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the _M_end of the same sequence in their second entry.

Ties are broken arbitrarily. See stable_multiway_merge for a variant that breaks ties by sequence number but is slower.

The first entries of the pairs (i.e. the begin iterators) will be moved forward.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- not using sentinels

Example:

```
int sequences[10][10];
for (int __i = 0; __i < 10; ++__i)
  for (int __j = 0; __i < 10; ++__j)
    sequences[__i][__j] = __j;

int __out[33];
std::vector<std::pair<int*> > seqs;
for (int __i = 0; __i < 10; ++__i)
  { seqs.push(std::make_pair<int*>(sequences[__i],
                                   sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int>(), 33);
```

Highly efficient 3-way merging procedure.

Merging is done with the algorithm implementation described by Peter Sanders. Basically, the idea is to minimize the number of necessary comparison after merging an element. The implementation trick that makes this fast is that the order of the sequences is stored in the instruction pointer (translated into labels in C++).

This works well for merging up to 4 sequences.

Note that making the merging stable does *not* come at a performance hit.

Whether the merging is done guarded or unguarded is selected by the used iterator class.

Merge the sequences specified by seqs_begin and __seqs_end into __target. __seqs_begin and __seqs_end must point to a sequence of pairs. These pairs must contain an iterator to the beginning of a sequence in their first entry and an iterator the _M_end of the same sequence in their second entry.

The output sequence has to provide enough space for all elements that are written to it.

This function will merge the input sequences:

- not stable
- parallel, depending on the input size and Settings
- using sampling for splitting
- using sentinels

You have to take care that the element the _M_end iterator points to is readable and contains a value that is greater than any other non-sentinel value in all sequences.

Example:

```
int sequences[10][11];
```

```
for (int __i = 0; __i < 10; ++__i)
  for (int __j = 0; __i < 11; ++__j)
    sequences[__i][__j] = __j; // __last one is sentinel!

int __out[33];
std::vector<std::pair<int*> > seqs;
for (int __i = 0; __i < 10; ++__i)
  { seqs.push(std::make_pair<int*>(sequences[__i],
                                   sequences[__i] + 10)) }

multiway_merge(seqs.begin(), seqs.end(), __target, std::less<int>(), 33);
```

Precondition

All input sequences must be sorted.
Target must provide enough space to merge out length elements or the number of elements in all sequences, whichever is smaller.
For each __i, __seqs_begin[__i].second must be the end marker of the sequence, but also reference the one more __sentinel element.

Postcondition

[__target, return __value) contains merged __elements from the input sequences.
return __value - __target = min(__length, number of elements in all sequences).

3.7.1 Detailed Description

3.8 __gnu_sequential Namespace Reference

3.8.1 Detailed Description

GNU sequential classes for public use.

3.9 abi Namespace Reference

3.9.1 Detailed Description

The cross-vendor C++ Application Binary Interface. A namespace alias to __cxxabiv1, but user programs should use the alias 'abi'. A brief overview of an ABI is given in the libstdc++ FAQ, question 5.8 (you may have a copy of the FAQ locally, or you can view the online version at http://gcc.gnu.org/onlinedocs/libstdc++/faq.html#5_8).

GCC subscribes to a cross-vendor ABI for C++, sometimes called the IA64 ABI because it happens to be the native ABI for that platform. It is summarized at http://www.codesourcery.com/cxx-abi/ along with the current specification.

For users of GCC greater than or equal to 3.x, entry points are available in <cxxabi.h>, which notes, *'It is not normally necessary for user programs to include this header, or use the entry points directly. However, this header is available should that be needed.'*

Standard Stream Objects

The <iostream> header declares the eight standard stream objects. For other declarations, see http://gcc.gnu.org/onlinedocs/libstdc++/manual/io.html *and the I/O forward declarations*

They are required by default to cooperate with the global C library's `FILE` *streams, and to be available during program startup and termination. For more information, see the section of the manual linked to above.*

3.10.4.7 template<typename _EuclideanRingElement > constexpr _EuclideanRingElement std::__gcd (_EuclideanRingElement __m, _EuclideanRingElement __n)

Definition at line 1219 of file stl_algo.h.

3.10.4.8 template<typename _IntType , typename _UniformRandomBitGenerator > pair<_IntType, _IntType> std::__gen_two_uniform_ints (_IntType __b0, _IntType __b1, _UniformRandomBitGenerator && __g)

Generate two uniformly distributed integers using a single distribution invocation.

Parameters

__b0	The upper bound for the first integer.
__b1	The upper bound for the second integer.
__g	A UniformRandomBitGenerator.

Returns

A pair (i, j) with i and j uniformly distributed over [0, __b0) and [0, __b1), respectively.

Requires: __b0 * __b1 <= __g.max() - __g.min().

Using uniform_int_distribution with a range that is very small relative to the range of the generator ends up wasting potentially expensively generated randomness, since uniform_int_distribution does not store leftover randomness between invocations.

If we know we want two integers in ranges that are sufficiently small, we can compose the ranges, use a single distribution invocation, and significantly reduce the waste.

Returns

Reinventing the wheel, but this time with prettier spokes!

This function tries to obtain storage for `__len` adjacent Tp objects. The objects themselves are not constructed, of course. A pair<> is returned containing *the buffer s address and capacity (in the units of sizeof(_Tp)), or a pair of 0 values if no storage can be obtained.* Note that the capacity obtained may be less than that requested if the memory is unavailable; you should compare len with the .second return value.

Character string extractors.

Parameters

__in	An input stream.
__s	A pointer to a character array.

Returns

__in

Behaves like one of the formatted arithmetic extractors described in std::basic_istream. After constructing a sentry object with good status, this function extracts up to `n` characters and stores them into the array starting at *__s*. `n` is defined as:

- if `width()` is greater than zero, `n` is width() otherwise
- `n` is *the number of elements of the largest array of* `*`
- *`char_type` that can store a terminating `eos`.*
- [27.6.1.2.3]/6

Characters are extracted and stored until one of the following happens:

- `n-1` characters are stored
- EOF is reached
- the next character is whitespace according to the current locale
- the next character is a null byte (i.e., `charT()`)

`width(0)` is then called for the input stream.

3.10.4.272 template<typename _CharT , typename _Traits > basic_istream< _CharT, _Traits > & std::ws (basic_istream< _CharT, _Traits > & __is)

Quick and easy way to eat whitespace.

This manipulator extracts whitespace characters, stopping when the next character is non-whitespace, or when the input sequence is empty. If the sequence is empty, `eofbit` is set in the stream, but not `failbit`.

The current locale is used to distinguish whitespace characters.

Example:

```
MyClass  mc;

std::cin >> std::ws >> mc;
```

will skip leading whitespace before calling operator>> on cin and your object. Note that the same effect can be achieved by creating a std::basic_istream::sentry inside your definition of operator>>.

3.11.1 Detailed Description

GNU debug code, replaces standard behavior with debug behavior. Macros and namespaces used by the implementation outside of debug wrappers to verify certain properties. The __glibcxx_requires_xxx macros are merely wrappers around the __glibcxx_check_xxx wrappers when we are compiling with debug mode, but disappear when we are in release mode so that there is no checking performed in, e.g., the standard library algorithms.

3.17.1 Detailed Description

ISO C++ 2014 namespace for suffixes for duration literals.

These suffixes can be used to create `chrono::duration` values with tick periods of hours, minutes, seconds, milliseconds, microseconds or nanoseconds. For example, `std::chrono::seconds(5)` can be written as `5s` after making the suffix visible in the current scope. The suffixes can be made visible by a using-directive or using-declaration such as:

- `using namespace std::chrono_literals;`
- `using namespace std::literals;`
- `using namespace std::chrono;`
- `using namespace std;`
- `using std::chrono_literals::operator""s;`

The result of these suffixes on an integer literal is one of the standard typedefs such as `std::chrono::hours`. The result on a floating-point literal is a duration type with the specified tick period and an unspecified floating-point representation, for example `1.5e2ms` might be equivalent to `chrono::duration<long double, chrono::milli>(1.5e2)`.

3.19.4 Variable Documentation

3.19.4.1 constexpr syntax_option_type std::regex_constants::__polynomial [inline]

Extension: Ensure both space complexity of compiled regex and time complexity execution are not exponential. If specified in a regex with back-references, the exception regex_constants::error_complexity will be thrown.

Definition at line 179 of file regex_constants.h.

3.19.4.2 constexpr syntax_option_type std::regex_constants::awk [inline]

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility awk in IEEE Std 1003.1-2001. This option is identical to syntax_option_type extended, except that C-style escape sequences are supported. These sequences are: \\, \a, \b, \f, \n, \r, \t , \v, \&apos„ &apos„ and \ddd (where ddd is one, two, or three octal digits).

Definition at line 152 of file regex_constants.h.

3.19.4.3 constexpr syntax_option_type std::regex_constants::basic [inline]

Specifies that the grammar recognized by the regular expression engine is that used by POSIX basic regular expressions in IEEE Std 1003.1-2001, Portable Operating System Interface (POSIX), Base Definitions and Headers, Section 9, Regular Expressions [IEEE, Information Technology – Portable Operating System Interface (POSIX), IEEE Standard 1003.1-2001].

Definition at line 132 of file regex_constants.h.

3.19.4.4 constexpr syntax_option_type std::regex_constants::collate [inline]

Definition at line 111 of file regex_constants.h.

3.19.4.5 constexpr syntax_option_type std::regex_constants::ECMAScript [inline]

Specifies that the grammar recognized by the regular expression engine is that used by ECMAScript in ECMA-262 [Ecma International, ECMAScript Language Specification, Standard Ecma-262, third edition, 1999], as modified in section [28.13]. This grammar is similar to that defined in the PERL scripting language but extended with elements found in the POSIX regular expression grammar.

Definition at line 122 of file regex_constants.h.

3.19.4.6 constexpr syntax_option_type std::regex_constants::egrep [inline]

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility grep when given the -E option in IEEE Std 1003.1-2001. This option is identical to syntax_option_type extended, except that newlines are treated as whitespace.

Definition at line 170 of file regex_constants.h.

3.19.4.7 constexpr syntax_option_type std::regex_constants::extended [inline]

Specifies that the grammar recognized by the regular expression engine is that used by POSIX extended regular expressions in IEEE Std 1003.1-2001, Portable Operating System Interface (POSIX), Base Definitions and Headers, Section 9, Regular Expressions.

Definition at line 141 of file regex_constants.h.

3.19.4.8 constexpr match_flag_type std::regex_constants::format_default [inline]

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the ECMAScript replace function in ECMA- 262 [Ecma International, ECMAScript Language Specification, Standard Ecma-262, third edition, 1999], part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression are located and replaced, and sections of the input that did not match the expression are copied unchanged to the output string.

Format strings (from ECMA-262 [15.5.4.11]):

- $$ The dollar-sign itself ($)
- $& The matched substring.
- $‘ The portion of *string* that precedes the matched substring. This would be match_results::prefix().
- $’ The portion of *string* that follows the matched substring. This would be match_results::suffix().
- $n The nth capture, where n is in [1,9] and $n is not followed by a decimal digit. If n <= match_results::size() and the nth capture is undefined, use the empty string instead. If n > match_results::size(), the result is implementation-defined.
- $nn The nnth capture, where nn is a two-digit decimal number on [01, 99]. If nn <= match_results::size() and the nth capture is undefined, use the empty string instead. If nn > match_results::size(), the result is implementation-defined.

Definition at line 346 of file regex_constants.h.

3.19.4.9 constexpr match_flag_type std::regex_constants::format_first_only [inline]

When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.

Definition at line 370 of file regex_constants.h.

3.19.4.10 constexpr match_flag_type std::regex_constants::format_no_copy [inline]

During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.

Definition at line 363 of file regex_constants.h.

3.19.4.11 constexpr match_flag_type std::regex_constants::format_sed [inline]

When a regular expression match is to be replaced by a new string, the new string is constructed using the rules used by the POSIX sed utility in IEEE Std 1003.1- 2001 [IEEE, Information Technology – Portable Operating System Interface (POSIX), IEEE Standard 1003.1-2001].

Definition at line 355 of file regex_constants.h.

3.19.4.12 constexpr syntax_option_type std::regex_constants::grep [inline]

Specifies that the grammar recognized by the regular expression engine is that used by POSIX utility grep in IEEE Std 1003.1-2001. This option is identical to syntax_option_type basic, except that newlines are treated as whitespace.

Definition at line 161 of file regex_constants.h.

3.19.4.13 constexpr syntax_option_type std::regex_constants::icase [inline]

Specifies that the matching of regular expressions against a character sequence shall be performed without regard to case.

Definition at line 87 of file regex_constants.h.

3.19.4.14 constexpr match_flag_type std::regex_constants::match_any [inline]

If more than one match is possible then any match is an acceptable result.

Definition at line 297 of file regex_constants.h.

3.19.4.15 constexpr match_flag_type std::regex_constants::match_continuous [inline]

The expression only matches a sub-sequence that begins at first .

3.19.4.16 constexpr match_flag_type std::regex_constants::match_default [inline]

The default matching rules.

Definition at line 260 of file regex_constants.h.

3.19.4.17 constexpr match_flag_type std::regex_constants::match_not_bol [inline]

The first character in the sequence [first, last) is treated as though it is not at the beginning of a line, so the character (^) in the regular expression shall not match [first, first).

Definition at line 268 of file regex_constants.h.

3.19.4.18 constexpr match_flag_type std::regex_constants::match_not_bow [inline]

The expression \b is not matched against the sub-sequence [first,first).

Definition at line 283 of file regex_constants.h.

3.19.4.19 constexpr match_flag_type std::regex_constants::match_not_eol [inline]

The last character in the sequence [first, last) is treated as though it is not at the end of a line, so the character ($) in the regular expression shall not match [last, last).

Definition at line 276 of file regex_constants.h.

3.19.4.20 constexpr match_flag_type std::regex_constants::match_not_eow [inline]

The expression \b should not be matched against the sub-sequence [last,last).

3.19.4.21 constexpr match_flag_type std::regex_constants::match_not_null [inline]

The expression does not match an empty sequence.

Definition at line 303 of file regex_constants.h.

3.19.4.22 constexpr match_flag_type std::regex_constants::match_prev_avail [inline]

–first is a valid iterator position. When this flag is set then the flags match_not_bol and match_not_bow are ignored by the regular expression algorithms 28.11 and iterators 28.12.

Definition at line 317 of file regex_constants.h.

3.19.4.23 constexpr syntax_option_type std::regex_constants::nosubs [inline]

Specifies that when a regular expression is matched against a character container sequence, no sub-expression matches are to be stored in the supplied match_results structure.

Definition at line 95 of file regex_constants.h.

3.19.4.24 constexpr syntax_option_type std::regex_constants::optimize [inline]

Specifies that the regular expression engine should pay more attention to the speed with which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.

Definition at line 104 of file regex_constants.h.

4.10.1 Detailed Description

Base type for atomic_flag.

Base type is POD with data, allowing atomic_flag to derive from it and meet the standard layout type requirement. In addition to compatibility with a C interface, this allows different implementations of atomic_flag to use the same atomic operation functions, via a standard conversion to the __atomic_flag_base argument.

template<typename _InternT, typename _ExternT, typename _StateT>class std::__codecvt_abstract_base< _InternT, _ExternT, _StateT >

Convert from internal to external character set.

Converts input string of intern_type to output string of extern_type. This function is a hook for derived classes to change the value returned.

Implemented in std::codecvt< char32_t, char, mbstate_t >, std::codecvt< char16_t, char, mbstate_t >, std::codecvt< wchar_t, char, mbstate_t >, std::codecvt< char, char, mbstate_t >, std::codecvt< _InternT, _ExternT, _StateT >, std::codecvt< _Elem, char, mbstate_t >, and std::codecvt< _InternT, _ExternT, encoding_state >.

Referenced by std::__codecvt_abstract_base< char32_t, char, mbstate_t >::out().

4.14.2.2 template<typename _InternT, typename _ExternT, typename _StateT> result std::__codecvt_abstract_base< _InternT, _ExternT, _StateT >::in (state_type & *__state*, const extern_type * *__from*, const extern_type * *__from_end*, const extern_type *& *__from_next*, intern_type * *__to*, intern_type * *__to_end*, intern_type *& *__to_next*) const [inline]

Convert from external to internal character set.

Converts input string of extern_type to output string of intern_type. This is analogous to mbsrtowcs. It does this by calling codecvt::do_in.

The source and destination character sets are determined by the facet's locale, internal and external types.

The characters in [from,from_end) are converted and written to [to,to_end). from_next and to_next are set to point to the character following the last successfully converted character, respectively. If the result needed no conversion, from_next and to_next are not affected.

The *state* argument should be initialized if the input is at the beginning and carried from a previous call if continuing conversion. There are no guarantees about how *state* is used.

The result returned is a member of codecvt_base::result. If all the input is converted, returns codecvt_base::ok. If no conversion is necessary, returns codecvt_base::noconv. If the input ends early or there is insufficient space in the output, returns codecvt_base::partial. Otherwise the conversion failed and codecvt_base::error is returned.

Parameters

__state	Persistent conversion state data.
__from	Start of input.
__from_end	End of input.
__from_next	Returns start of unconverted data.
__to	Start of output buffer.
__to_end	End of output buffer.
__to_next	Returns start of unused output area.

Returns

codecvt_base::result.

Definition at line 196 of file codecvt.h.

4.14.2.3 template<typename _InternT, typename _ExternT, typename _StateT> result std::__codecvt_abstract_base< _InternT, _ExternT, _StateT >::out (state_type & *__state,* const intern_type * *__from,* const intern_type * *__from_end,* const intern_type *& *__from_next,* extern_type * *__to,* extern_type * *__to_end,* extern_type *& *__to_next*) const [inline]

Convert from internal to external character set.

Converts input string of intern_type to output string of extern_type. This is analogous to wcsrtombs. It does this by calling codecvt::do_out.

The source and destination character sets are determined by the facet's locale, internal and external types.

The characters in [from,from_end) are converted and written to [to,to_end). from_next and to_next are set to point to the character following the last successfully converted character, respectively. If the result needed no conversion, from_next and to_next are not affected.

The *state* argument should be initialized if the input is at the beginning and carried from a previous call if continuing conversion. There are no guarantees about how *state* is used.

The result returned is a member of codecvt_base::result. If all the input is converted, returns codecvt_base::ok. If no conversion is necessary, returns codecvt_base::noconv. If the input ends early or there is insufficient space in the output, returns codecvt_base::partial. Otherwise the conversion failed and codecvt_base::error is returned.

Parameters

__state	Persistent conversion state data.
__from	Start of input.
__from_end	End of input.
__from_next	Returns start of unconverted data.
__to	Start of output buffer.
__to_end	End of output buffer.
__to_next	Returns start of unused output area.

Returns

codecvt_base::result.

Definition at line 116 of file codecvt.h.

4.14.2.4 template<typename _InternT, typename _ExternT, typename _StateT> result std::__codecvt_abstract_base< _InternT, _ExternT, _StateT >::unshift (state_type & *__state,* extern_type * *__to,* extern_type * *__to_end,* extern_type *& *__to_next*) const [inline]

Reset conversion state.

Writes characters to output that would restore *state* to initial conditions. The idea is that if a partial conversion occurs, then the converting the characters written by this function would leave the state in initial conditions, rather than partial conversion state. It does this by calling codecvt::do_unshift().

For example, if 4 external characters always converted to 1 internal character, and input to in() had 6 external characters with state saved, this function would write two characters to the output and set the state to initialized conditions.

The source and destination character sets are determined by the facet's locale, internal and external types.

The result returned is a member of codecvt_base::result. If the state could be reset and data written, returns codecvt_base::ok. If no conversion is necessary, returns codecvt_base::noconv. If the output has insufficient space, returns codecvt_base::partial. Otherwise the reset failed and codecvt_base::error is returned.

Parameters

__state	Persistent conversion state data.
__to	Start of output buffer.
__to_end	End of output buffer.
__to_next	Returns start of unused output area.

Returns

codecvt_base::result.

4.38.1 Detailed Description

template<typename _Tp>class __gnu_cxx::__detail::__mini_vector< _Tp >

__mini_vector<> is a stripped down version of the full-fledged std::vector<>.

It is to be used only for built-in types or PODs. Notable differences are:

1. Not all accessor functions are present.
2. Used ONLY for PODs.
3. No Allocator template argument. Uses operator new() to get memory, and operator delete() to free it. Caveat: The dtor does NOT free the memory allocated, so this a memory-leaking vector!

True if the type is integer.

Definition at line 226 of file limits.

4.48.2.12 constexpr bool std::__numeric_limits_base::is_modulo [static]

True if the type is *modulo*. A type is modulo if, for any operation involving +, -, or $*$ on values of that type whose result would fall outside the range [min(),max()], the value returned differs from the true value by an integer multiple of max() - min() + 1. On most machines, this is false for floating types, true for unsigned integers, and true for signed integers. See PR22200 about signed integers.

4.54.1 Detailed Description

Base class for __pool_alloc.

Uses various allocators to fulfill underlying requests (and makes as few requests as possible when in default high-speed pool mode).

Important implementation properties: 0. If globally mandated, then allocate objects from new

1. If the clients request an object of size > _S_max_bytes, the resulting object will be obtained directly from new

2. In all other cases, we allocate an object of size exactly _S_round_up(requested_size). Thus the client has enough size information that we can return the object to the proper free list without permanently losing part of the object.

4.56.1 Detailed Description

template<typename _CharT, typename _Traits, typename _Alloc>class __gnu_cxx::__rc_string_base< _CharT, _Traits, _Alloc >

Documentation? What's that? Nathan Myers ncm@cantrip.org.

A string looks like this:

```
                                    [_Rep]
                                    _M_length
[__rc_string_base<char_type>]       _M_capacity
_M_dataplus                         _M_refcount
_M_p ---------------->              unnamed array of char_type
```

Where the _M_p points to the first character in the string, and you cast it to a pointer-to-_Rep and subtract 1 to get a pointer to the header.

This approach has the enormous advantage that a string object requires only one allocation. All the ugliness is confined within a single pair of inline functions, which each compile to a single *add* instruction: _Rep::_M_refdata(), and __rc_string_base::_M_rep(); and the allocation function which gets a block of raw bytes and with room enough and constructs a _Rep object at the front.

The reason you want _M_data pointing to the character array and not the _Rep is so that the debugger can see the string contents. (Probably we should add a non-inline member to get the _Rep for the debugger to use, so users can check the actual string length.)

Note that the _Rep object is a POD so that you can have a static *empty string* _Rep object already *constructed* before static constructors have run. The reference-count encoding is chosen so that a 0 indicates one reference, so you never try to destroy the empty-string _Rep object.

All but the last paragraph is considered pretty conventional for a C++ string implementation.

Attempt to preallocate enough memory for specified number of characters.

Parameters

__res_arg	Number of characters required.

Exceptions

std::length_error	If *__res_arg* exceeds `max_size()`.

This function attempts to reserve enough memory for the string to hold the specified number of characters. If the number requested is more than max_size(), length_error is thrown.

The advantage of this function is that if optimal code is a necessity and the user can determine the string length that will be required, the user can reserve the memory in advance, and thus prevent a possible reallocation of memory and copying of string data.

Parameters

__n	Number of characters the string should contain.
__c	Character to fill any new elements.

This function will resize the string to the specified number of characters. If the number is smaller than the string's current size the string is truncated, otherwise the string is extended and new elements are set to *__c*.

Parameters

__n	Number of characters the string should contain.

This function will resize the string to the specified length. If the new size is smaller than the string's current size the string is truncated, otherwise the string is extended and new characters are default-constructed. For basic types such as char, this means setting them to 0.

Public Types

- typedef _ToType::element_type * **type**

4.76.1 Detailed Description

template<typename _ToType>struct __gnu_cxx::_Caster< _ToType >

These functions are here to allow containers to support non standard pointer types. For normal pointers, these resolve to the use of the standard cast operation. For other types the functions will perform the appropriate cast to/from the custom pointer class so long as that class meets the following conditions: 1) has a typedef element_type which names tehe type it points to. 2) has a get() const method which returns element_type*. 3) has a constructor which can take one element_type* argument. This type supports the semantics of the pointer cast operators (below.)

template<typename _CharT>struct __gnu_cxx::_Char_types< _CharT >

Mapping from character type to associated types.

Note

This is an implementation class for the generic version of char_traits. It defines int_type, off_type, pos_type, and state_type. By default these are unsigned long, streamoff, streampos, and mbstate_t. Users who need a different set of types, but who don't need to change the definitions of any function defined in char_traits, can specialize __gnu_cxx::_Char_types while leaving __gnu_cxx::char_traits alone.

template<typename _Tp, typename _Alloc>class std::_Deque_base< _Tp, _Alloc >

Deque base class. This class provides the unified face for deque's allocation. This class's constructor and destructor allocate and deallocate (but do not initialize) storage. This makes exception safety easier.

Nothing in this class ever constructs or destroys an actual Tp element. (Deque handles that itself.) Only/All memory management is performed here.

4.83.1 Detailed Description

template<typename _Tp, typename _Ref, typename _Ptr>struct std::_Deque_iterator< _Tp, _Ref, _Ptr >

A deque::iterator.

Quite a bit of intelligence here. Much of the functionality of deque is actually passed off to this class. A deque holds two of these internally, marking its valid range. Access to elements is done as offsets of either of those two, relying on operator overloading in this class.

All the functions are op overloads except for _M_set_node.

4.107 std::__detail::_Hash_code_base< _Key, _Value, _ExtractKey, _H1, _H2, _Hash, __cache_hash_code > Struct Template Reference

4.107.1 Detailed Description

template<typename _Key, typename _Value, typename _ExtractKey, typename _H1, typename _H2, typename _Hash, bool __cache_hash_code>struct std::__detail::_Hash_code_base< _Key, _Value, _ExtractKey, _H1, _H2, _Hash, __cache_hash_code >

Primary class template _Hash_code_base.

Encapsulates two policy issues that aren't quite orthogonal. (1) the difference between using a ranged hash function and using the combination of a hash function and a range-hashing function. In the former case we don't have such things as hash codes, so we have a dummy type as placeholder. (2) Whether or not we cache hash codes. Caching hash codes is meaningless if we have a ranged hash function.

We also put the key extraction objects here, for convenience. Each specialization derives from one or more of the template parameters to benefit from Ebo. This is important as this type is inherited in some cases by the _Local_iterator_base type used to implement local_iterator and const_local_iterator. As with any iterator type we prefer to make it as small as possible.

Primary template is unused except as a hook for specializations.

4.116.1 Detailed Description

template<typename _Key, typename _Value, typename _Alloc, typename _ExtractKey, typename _Equal, typename _H1, typename _H2, typename _Hash, typename _RehashPolicy, typename _Traits>class std::_Hashtable< _Key, _Value, _Alloc, _ExtractKey, _Equal, _H1, _H2, _Hash, _RehashPolicy, _Traits >

Primary class template _Hashtable.

Template Parameters

_Value	CopyConstructible type.
_Key	CopyConstructible type.
_Alloc	An allocator type ([lib.allocator.requirements]) whose _Alloc::value_type is _Value. As a conforming extension, we allow for _Alloc::value_type != _Value.
_ExtractKey	Function object that takes an object of type _Value and returns a value of type _Key.
_Equal	Function object that takes two objects of type k and returns a bool-like value that is true if the two objects are considered equal.
_H1	The hash function. A unary function object with argument type _Key and result type size_t. Return values should be distributed over the entire range [0, numeric_limits<size_t>:max()].
_H2	The range-hashing function (in the terminology of Tavori and Dreizin). A binary function object whose argument types and result type are all size_t. Given arguments r and N, the return value is in the range [0, N).
_Hash	The ranged hash function (Tavori and Dreizin). A binary function whose argument types are _Key and size_t and whose result type is size_t. Given arguments k and N, the return value is in the range [0, N). Default: hash(k, N) = h2(h1(k), N). If _Hash is anything other than the default, _H1 and _H2 are ignored.
_RehashPolicy	Policy class with three members, all of which govern the bucket count. _M_next_bkt(n) returns a bucket count no smaller than n. _M_bkt_for_elements(n) returns a bucket count appropriate for an element count of n. _M_need_rehash(n_bkt, n_elt, n_ins) determines whether, if the current bucket count is n_bkt and the current element count is n_elt, we need to increase the bucket count. If so, returns make_pair(true, n), where n is the new bucket count. If not, returns make_pair(false, <anything>)
_Traits	Compile-time class with three boolean std::integral_constant members: __cache_hash_code, __constant_iterators, __unique_keys.

Each _Hashtable data structure has:

- _Bucket[] _M_buckets
- _Hash_node_base _M_before_begin
- size_type _M_bucket_count
- size_type _M_element_count

with _Bucket being _Hash_node* and _Hash_node containing:

- _Hash_node* _M_next
- Tp _M_value
- size_t _M_hash_code if cache_hash_code is true

In terms of Standard containers the hashtable is like the aggregation of:

- std::forward_list<_Node> containing the elements
- std::vector<std::forward_list<_Node>::iterator> representing the buckets

The non-empty buckets contain the node before the first node in the bucket. This design makes it possible to implement something like a std::forward_list::insert_after on container insertion and std::forward_list::erase_after on container erase calls. _M_before_begin is equivalent to std::forward_list::before_begin. Empty buckets contain nullptr. Note that

one of the non-empty buckets contains &_M_before_begin which is not a dereferenceable node so the node pointer in a bucket shall never be dereferenced, only its next node can be.

Walking through a bucket's nodes requires a check on the hash code to see if each node is still in the bucket. Such a design assumes a quite efficient hash functor and is one of the reasons it is highly advisable to set __cache_hash_code to true.

The container iterators are simply built from nodes. This way incrementing the iterator is perfectly efficient independent of how many empty buckets there are in the container.

On insert we compute the element's hash code and use it to find the bucket index. If the element must be inserted in an empty bucket we add it at the beginning of the singly linked list and make the bucket point to _M_before_begin. The bucket that used to point to _M_before_begin, if any, is updated to point to its new before begin node.

On erase, the simple iterator design requires using the hash functor to get the index of the bucket to update. For this reason, when __cache_hash_code is set to false the hash functor must not throw and this is enforced by a static assertion.

Functionality is implemented by decomposition into base classes, where the derived _Hashtable class is used in _Map-_base, _Insert, _Rehash_base, and _Equality base classes to access the "this" pointer. _Hashtable_base is used in the base classes as a non-recursive, fully-completed-type so that detailed nested type information, such as iterator type and node type, can be used. This is similar to the "Curiously Recurring Template Pattern" (CRTP) technique, but uses a reconstructed, not explicitly passed, template pattern.

Base class templates are:

- __detail::_Hashtable_base
- __detail::_Map_base
- __detail::_Insert
- __detail::_Rehash_base
- __detail::_Equality

struct _Hashtable_traits

Important traits for hash tables.

Template Parameters

_Cache_hash_code	Boolean value. True if the value of the hash function is stored along with the value. This is a time-space tradeoff. Storing it may improve lookup speed by reducing the number of times we need to call the _Hash or _Equal functors.

_Constant_iterators	Boolean value. True if iterator and const_iterator are both constant iterator types. This is true for unordered_set and unordered_multiset, false for unordered_map and unordered_multimap.
_Unique_keys	Boolean value. True if the return value of _Hashtable::count(k) is always at most one, false if it may be an arbitrary number. This is true for unordered_set and unordered_map, false for unordered_multiset and unordered_multimap.
